Reason

All 2 answers converge on one theme: "Look, the allocation itself feels right for my situation - 40% bonds and only 55% stocks is appropriately conservative given I'm a risk-averse parent with young kids and family obligations, plus I'm working in finance so I know what a real market crash looks like. The problem is that this backtest is basically useless for my decision-making because it completely skips the 2008 crisis. I deliberately chose 2000 as my start date specifically to capture that brutal drawdown period, but the tool's free tier and data limitations chopped it down to just 2017-2026. That's like test-driving a car only on sunny days when you live somewhere with harsh winters - it tells me nothing about whether I can actually stomach the losses during a real crisis when I'm worrying about my kids' future and bills. The 8.44% return looks nice on paper but it's inflated by missing the worst years. I need to see this portfolio survive 2008 with a max drawdown I could realistically tolerate (maybe 25-30% max) before I'd actually put my high-income savings into it. Until I can validate that, I'm staying cautious and this remains a 'maybe' allocation, not a commitment. The conservative philosophy is right, but the evidence is incomplete. ? That's just being realistic about what I don't know."

Sample answers

Disclosure text

All 2 answers converge on one theme: "Backtest period limited to 10 years (Jan 2017 - Jun 2026) instead of intended 20 years due to free tier account restrictions and VXUS data availability starting only from Feb 2011 | The backtest completely misses the 2008 financial crisis, which would have been the most severe stress test for this portfolio allocation over a true 20-year horizon from 2006 | Backtest period (2017-2026) captures primarily a bull market with only one significant drawdown in 2022 (-23.86%), which may present an overly optimistic picture of long-term performance | End date shows June 2026, which extends into the future beyond the current date, meaning some results may include projected or simulated data rather than purely historical returns | The 11.64% CAGR may not be sustainable over a full market cycle including major crises - historical averages including severe downturns would likely be lower | Maximum drawdown of -23.86% is moderate, but a 2008-style crisis could produce drawdowns exceeding -50% for an 85% equity allocation, which would be a much more challenging test of my actual risk tolerance".
